Objectives: Learning disabilities can cause serious communication and socio-emotional disorders in students. Teachers, as specialists who are in direct contact with students on a daily basis, have an important role in identifying and referring students suspected of these disabilities. Therefore, this study investigated the role of primary school teachers’ awareness and attitude about the signs and symptoms of learning disabilities on the referral of students of Ahvaz City, Iran to speech therapy centers.

Methods: This case-control study was conducted on 165 elementary school teachers in Ahvaz in 2016-2017. The teacher’s awareness questionnaire was used to determine the teachers’ awareness level. A logistic regression test was used to explore the role of teachers’ attributes on the referral of students to speech therapies.

Results: The mean total score of teachers’ awareness about students’ learning disabilities was significantly different in the case and control groups (P<0.05). Teachers’ awareness scores had a direct and significant relationship with working experience (P<0.05) and participation in educational workshops (P<0.05). However, there was no significant relationship between the teachers’ awareness score with age and gender (P>0.05).

Discussion: Teaching experience, educational level, history of participation in educational workshops and the teachers’ awareness of learning disabilities are critical factors in referring students to speech therapy centers. It is recommended that teachers participate in workshops at regular intervals to update their knowledge on this topic.
Highlights

- Teachers’ experience, their level of education, participation in workshops, and awareness of learning disabilities can directly affect their referral of students to speech therapy centers.

- The age and gender of teachers did not affect the rate of referral of students with learning disabilities to speech therapy centers.

Plain Language Summary

Learning disability of educational skills can cause communicational, emotional and social disorders. Teachers play a key role in diagnosing this problem in their students and referring them to special therapy centers. In this study, we considered those variables related to the teachers’ awareness on learning disability. Teachers’ work experience, their educational level, participation in educational workshops and awareness level of learning disability had main effect on referring students to speech therapy clinics.

1. Introduction

Learning disabilities are neurodegenerative disorders with a prevalence rate between 3% and 12% in elementary school students [1-4]. This rate was 11.4% among the third, fourth and fifth grade primary school students in Iran [5]. This rate was similar to that found in America [6]. Genetic factors and prenatal and postnatal conditions may cause learning disabilities [7].

The term “learning disability” was introduced by Samuel Kirk in 1962 [8]. According to the fifth edition of Diagnostic and Statistical Manual of Mental Disorders (DSM-V-TR, 2013), learning disabilities refer to the conditions when academic skills are greatly below the average range of expected scores based on the chronological age (e.g. at least 1.5 SD below the population mean score for age). The difference between intelligence and academic achievement scores in standardized reading, mathematical tests, and written expressions is basically lower than the chronological age, intellectual, and educational level. Learning disabilities significantly affect the academic achievement and daily living activities requiring reading, math or writing skills [9].

Lingeswaran (2013) introduced factors such as a history of language impairment, inability to carry out and maintain activities, weak purposefulness and novelty and the lack of socio-emotional maturity as predictors of learning disabilities [7]. Students with learning disabilities are usually not identified before the third and fourth grades. Consequently, they may miss learning and education opportunities due to secondary problems such as lack of concentration, hyperactivity, communication disorders and depression caused by learning disorders [5].

Most of the students with severe learning disabilities attend exceptional schools due to a misdiagnosis of intellectual disabilities. Those who attend public schools face many challenges in educational progress, which, unfortunately, is the result of 40% academic failure of these children [3, 5]. The later the disabilities are identified, the harder the rehabilitation will be. However, the identification and treatment of such children will lead to their 70% recovery [3, 4]. For this reason, since 1994, the training of students with special needs has become an international concern. Also, countries around the world have committed themselves to provide equal education services for students with special needs as their normal peers [5].

One of the most important strategies for an early age identification of these abnormalities is referring them (by primary school teachers) to rehabilitation practitioners including speech therapists, for accurate and comprehensive assessment and the final diagnosis of childhood learning disorder. This requires that teachers be aware of the signs and symptoms of the disorder and even carry out initial screening of the students [10]. Otherwise, the evaluation and diagnosis may be delayed or lead to undesirable outcomes. Therefore, the awareness and attitudes of primary school teachers about learning disorders are very important [11].

Some studies have reported that the teachers’ awareness of learning disabilities is low that results in many challenges in academic achievement of students [12-14]. Kataoka et al. (2004) studied the perception of teachers...
schools. Such programs help with identifying and diag-
special needs including learning disabilities in public
are held for teachers in order to educate children with

edge and attitudes of teachers of children with learning
disabilities. Initially, 59 students who were referred to
speech therapy clinics with the diagnosis of learning
disabilities by school teachers were selected by conve-
nience sampling method. Gender, age, and educational
background were identified. Then, the teachers who
identified these students and referred them to speech
therapy services were identified. A total of 45 elementary
public school teachers were identified and enrolled into
the case group. A demographic data questionnaire was
completed by them.

Abdi et al. reported that teachers’ awareness about
identification, categorization and the total awareness
of learning disabilities was significantly higher in female
teachers than male teachers. However, there was no sig-
nificant differences on the knowledge of rehabilitation
between male and female teachers. They concluded
that teachers with higher academic education had more
awareness about learning disabilities [13]. Arjmandi
and Kakabarei reported no significant differences be-
tween female and male teachers on the knowledge about
learning disabilities. They also reported that academic
education had no effect on the knowledge about learn-
ing disabilities [2]. Moothedath and Narasimha Vranda
(2015) also conducted a study on the knowledge of pri-
mary school teachers in India. In total, 200 teachers from
16 schools completed a questionnaire about teachers’
knowledge of learning disabilities. They emphasized
that teachers should increase their identification knowl-
gedge of students with learning disabilities [14].

In many countries, workshops and in-service programs
are held for teachers in order to educate children with
special needs including learning disabilities in public
schools. Such programs help with identifying and diag-
nosing these disorders in a timely manner [11]. There is
still a lack of time management for referring many stu-
dents with learning disabilities in Iran. It can be because
of the low awareness of teachers about these conditions.
Therefore, the present study investigated the role of
awareness and attitude of primary school teachers as well
as other demographic characteristics on the referral time
of students with learning disabilities to speech therapists.

2. Methods

The participants of the present study were the elemen-
tary school teachers in Ahwaz City, Iran. The sample size
required for the current study was determined using the
sample size determination by G*Power (\( \alpha = 0.05, \beta = 0.95, \)
d = 0.71). Finally, 165 teachers participated in this case-
control study and completed the questionnaire of knowl-
edge and attitudes of teachers of children with learning
disabilities. Characteristics such as teaching experience, degree,
gender, and history of participation in workshops con-
structed the main aspects of this questionnaire. Also,
120 primary school teachers of public schools were
randomly selected as the control group who completed
the demographic data questionnaire, as well. There were
also teachers in the control group who had a history of
students’ referral to the speech therapy centers, as well
as teachers without such history. After collecting the
demographic data, all teachers in the two groups com-
pleted the questionnaire for determining the knowledge
and awareness of elementary school teachers of students
with learning disabilities.

Psychometric properties of the questionnaire were inves-
tigated by Abdi et al. in Iran (2010). This questionnaire
consists of 3 subscales, including teachers’ knowledge of
the a. learning disabilities symptoms; b. symptoms cat-
ergization; and c. existing therapeutic approaches, to
improve learning disabilities in elementary school stu-
dents. This instrument consists of 34 items. The correct
and incorrect answers to each question are scored 1 and 0
respectively. The total score indicates the level of knowl-
edge and awareness in elementary school teachers of stu-
dent learning disabilities. Thus, a score of 0-10 reflects
low awareness, 11-20 moderate awareness, 21-30 desir-
able awareness, and over 30 very good awareness [13].

All of the teachers provided a consent form for partici-
pation in the current study. We explained the purposes
of our study to them. SPSS was used for statistical analysis.
Considering the normal distribution of data, Indepen-
dent t-test was used for between-group comparisons of
continuous quantitative variables. Spearman’s correla-
tion coefficient was used to determine the correlation
between teachers’ characteristics and their awareness
level and attitude. Binary logistic regression was used to
determine the role of teacher’s characteristics on the re-
feral or non-referral of the students to speech therapies.
The teachers’ gender, level of education, awareness level
and attitude scores, and their attendance to workshops
3. Results

The baseline characteristics of both groups of teachers are presented in Table 1. Table 2 presents the total mean and standard deviation scores of awareness and attitude of teachers of students with learning disabilities in the case and control groups. There was a significant difference between the scores of groups in the questionnaire (P<0.001).

According to Table 3, in both case and control groups, the awareness and attitude scores of teachers had a direct and significant relationship with the working experience (P<0.001) and the history of participation in workshops (P<0.001). In addition, in the control group, the awareness and attitude scores of teachers had a direct and significant relationship with their level of education (P=0.04). However, in the case and control groups, there was no significant correlation between the awareness score of teachers, age, and educational level. Furthermore, in the case group, there was no significant correlation between teachers’ awareness scores and educational level (P>0.05).

After performing initial analysis, the logistic regression test was used to determine the weight and role of each characteristic of the teachers on the referral or non-referral of students (Table 4). As presented, teaching experience, teacher’s educational level, awareness test scores and a history of workshop participation significantly affected the referral of students with suspected learning disabilities to speech therapies (P<0.003). However, the age and gender of teachers did not affect the rate of referral of students with learning disabilities to speech therapies (P>0.05).

4. Discussion

The current study determined the effective factors on the timely referral of students suspected of learning disabilities to speech therapy centers by elementary school teachers. The obtained results indicated that the level of awareness and attitude was different between the case and control groups regarding learning disabilities in the three areas of identification, classification, and rehabilitation (Table 2). Therefore, the Iranian teachers had a relatively low awareness of students’ learning disabilities.

This finding is in line with the studies by Kataoka et al. (2004), Moothedath and Narasimha Vranda (2015),
and Abdi et al. who found that primary school teachers had a low level of awareness about learning disabilities [12, 14]. However, these data were inconsistent with Jamal and Al-Khatib study findings. In this study, teachers had a moderate knowledge about learning disabilities. The reason of this result is the interaction of teachers with those who had activities in the field of learning disabilities, participating in training courses and, getting information from workshops, TV programs, radios, and learning disability journals [15].

The low level of teachers' awareness can be attributed to the incapability of teachers to identify invisible disabilities. Studies have reported that in the curriculum intended for Indian teachers, there are no specific curriculum or a workshop on signs and symptoms of children with learning disabilities. This can lead to a lack of awareness among teachers and consequently, lack of timely referral of students with special needs [13]. The case group teachers had a history of referring students suspected of learning disabilities to speech therapies.

To determine the reason of significant difference between the two groups, the subjects’ backgrounds were investigated. Comparisons revealed that factors such as teacher’s gender, educational level, and history of participation in workshops were different between the two groups (Table 1). In addition, the correlation analysis suggested a direct and significant correlation between the level of awareness and attitude of teachers with their work experience, educational level and workshops attendance. In addition, there was no significant correlation between the level of awareness and attitude of teachers, and age and gender (Table 3).

This finding is in line with Abdi et al. and Arjamndi studies [2, 13]. However, it was inconsistent with Bhavya and Kamala study [16, 17]. They also reported teachers with higher educational level had higher knowledge about learning disabilities. Arjamndi and Kakabarei also reported similar findings. They stated that education and gender had significant effects on teachers’ knowledge about learning disabilities [2].

Kamala reported that gender had no effect on teachers’ knowledge. He also demonstrated no significant differences between teachers with 1-5 years of teaching experience and those with more than 5 years of teaching experience in terms of knowledge about learning disabilities [17]. Bhavya also reported that educational level
and gender had no effects on teachers’ knowledge about learning disabilities [16]. Lingeswaran also reported that teaching experience had no effects on teachers’ knowledge about learning disabilities [7].

The regression analysis suggested that teachers’ teaching experience, their level of education, history of participation in workshops, and their awareness of learning disabilities can directly affect the referral of students to speech therapy centers by teachers. Obviously, teachers’ participation in workshops can familiarize them with the diagnoses, causes and the specialists for resolving learning disabilities [11]. Moreover, teachers with higher educational level learn more about the educational issues and learning conditions among students, in addition to their specialized courses [8]. Teaching experience is another important factor illustrating the impact of managing students’ issues. Certainly, one should not simply ignore the unique experiences of each teacher in dealing with students. The literature has also emphasized on the importance and impact of this issue on teachers’ awareness of the different conditions of students [13, 16].

To explaining the reason for this finding, it can be said that recognizing the field of learning disabilities in the education system of Iran is relatively new. In addition, it can be indicative of the neglect of educational planners to update teachers’ knowledge and motivation for self-learning [13]. Finally, the obtained results revealed that the higher the level of awareness and attitude of teachers about student learning disabilities, the more the students will be referred to appropriate centers. Therefore, it is important to increase the awareness of teachers by holding workshops, improving the educational level of teachers, and increasing their job experience besides increasing their awareness and attitudes about students’ learning disabilities. The aforementioned actions may lead to the timely referrals of such children to specialized centers to overcome their disabilities.

5. Conclusion

Teachers directly address the educational and behavioural issues of students. Thus, they play a key role in diagnosing, referring, and solving students’ problems. Creating a proper vision of these students is essential to have a suitable function for them. Treatment of these students will be a result of interaction between the family, teacher and therapist. Therefore, it is desirable for primary school teachers, as the most important levels of education, to have a thorough awareness of recognition of learning disabilities. This can be achieved through modification of teacher training programs and informing them via media on the needs of such children. In order to achieve this goal, workshops at regular intervals could be held. In addition, careful planning and the comprehensive support of the relevant authorities are required. Further research is required to more accurately assess teachers’ awareness. The lack of teacher awareness measurement subtests was a limitation to this study.

Ethical Considerations

Compliance with ethical guidelines

The present study was approved by the Ethics Committee of University of Ahvaz Jundishapur Medical Sciences (Code: IR.AJUMS.REC.1396.559).

Funding

The current article was part of a Bachelor dissertation of Ebtesam Hozeily and was financially supported by Musculoskeletal Rehabilitation Research Center, Ahvaz Jundishapur University of Medical Sciences.

Authors contributions

The authors contributions is as follows: Conceptualization: Peyman Zamani, Neda Tahmasebi and Negin Moradi; Formal analysis, investigated, writing review & editing: Peyman Zamani and Neda Tahmasebi; Writing-original draft preparation: Akram Ahmadi and Ebtesam Hozeily.
